Introduction

To facilitate implementation of the EAA Regulatory Rule (40E-63), software has been developed for tracking phosphorus loads at basin and farm levels. This report provides guidance for future use and maintenance of the software by SFWMD staff. It is anticipated that the procedures will be executed at a quarterly frequency to provide current information on phosphorus load reductions and compliance with the Rule. Some evolution of the software is expected to reflect changing conditions in the EAA (new inflows, outflows, measurement locations, farm permits, etc.) and to reflect needs for any new software features or algorithms which become apparent as the methodology is applied in the future. This report provides basic information on program structures, data structures, and updating procedures. All software has been developed for application on IBM PC-compatible computers. Descriptions of the algorithm for calculating basin loads and the models/equations used for testing compliance are contained in the Rule and are not repeated here. To supplement this report, many comment statements have been added to the workbooks and Fortran programs used in the calculations. Since the previous version of this documentation (May 1997), all workbooks have been converted from Lotus-123 (Rel. 4/5) to Excel 97.

Basin-Scale Calculations

Overview

Table 1 lists and describes data files and programs involved in basin-scale calculations. Primary steps include:

1. Retrieval of New Data. Daily flow, daily rainfall, and phosphorus concentration data are extracted from data bases maintained on the SFWMD's mainframe computers. Retrieval programs written in SQL are provided to extract the required data (Tables 2-4). The files are downloaded to a PC for subsequent processing.
2. Updating of Data Files. Historical flow, rainfall, and phosphorus data are merged with new data obtained in Step 1. Monthly total rainfall amounts are calculated from the daily rainfall files. All data files start in October 1978. File contents are summarized in Tables 2-4.

3. Phosphorus Load Calculations. A Fortran program (EAATPLD.FOR) codified in the Rule calculates monthly flows and phosphorus loads at several inflow/outflow points to/from the EAA. Total EAA runoff and phosphorus load are calculated on a monthly basis for the entire period of record. This version of the program differs from that published in the Rule only with respect to input / output formats and comment lines.
4. Compliance Calculations. An Excel 97 workbook (EAABASIN.XLS) calculates load reductions and tests for compliance. Monthly load and rainfall files generated in previous steps are accessed in these calculations. Several tabular and graphic output formats summarize current and historical results. Workbook contents are outlined in Table 5.

Once update files have been downloaded, all calculations are controlled from within the EAABASIN.XLS workbook. Portions of the workbook are referenced in farm-scale calculations. For this reason, basin calculations must be updated before farm-scale calculations can be updated.

Installing Basin Software

To install the basin software on a PC, create a new disk directory and copy all files to that directory. The software and data files require approximately 2 megabytes of free disk space. Load the EAABASIN.XLS workbook. The 'Menu' page appears (see Table 5). Enter the name of the disk directory containing the Basin software and data files (e.g., "C:\EAABASIN") at the top of the 'Menu' page. Save the workbook.

Supporting macros are stored as Visual Basic Code attached to EAABASIN.XLS workbook. These are transparent to the user. To view the code, select "Tools Macros VisualBasicEditor", then select 'Modules/Module1' under VBA Project EAAFARM.XLS from the Project window in the upper left corner of the screen.

Updating Basin Calculations

Periodic updates of basin calculations will normally involve the following procedures:

1. Submit retrieval programs (EAARAIN.COM, EAAFLOW.COM, EAATP.COM) to the SFWMD mainframe and download the corresponding

output files (EAARAIN.SPL, EAAFLOW.SPL, and EAATP.SPL, respectively). A date range is specified in each program. The default range is set to retrieve all data after the end of the Rule Base Period (from October 1, 1991 to December 31, 2020). In this way, each update will reflect recent data, as well as any changes or corrections which may have been made to SFWMD's hydrologic or water quality data bases after the Base Period. The downloaded files should be placed in the PC disk directory containing the Basin software and data files.

2. Load the EAABASIN.XLS workbook. The 'Menu' page appears (see Table 5). If not performed during the installation step (see above), enter the name of the disk directory containing the Basin software and data files (e.g., "C:\EAABASIN") at the top of the 'Menu' page.
3. Update the 'Areas' page to reflect acreage removed from the EAA drainage basin, as specified in the Rule. Based upon current interpretations of the Rule, adjustment for reductions in area will be necessary only after the Stormwater Treatment Areas are constructed.
4. Click the "Update Files" button located on the 'Menu' page. This executes a DOS batch program (GO.BAT) which updates data files and calculates monthly basin loads (Table 6). Alternatively, this step can be conducted from the DOS command prompt by entering ">GO". The batch procedure will terminate early if errors are encountered in updating data files. The batch procedure produces a log file "EAA.LOG" which traces the load calculations for each station. If difficulties are encountered, this file can be examined to help identify error sources. When the batch program is completed, the DOS window must be closed manually to return to the workbook.
5. Click the "Update Workbook" button on the 'Menu' page. Compliance calculations ('Monthly' & 'Yearly' pages), output tables, and graphs are updated. Four files produced in the previous step are stored in the following pages of the workbook:

EAARAINM.FIX - monthly rainfall	RainUpdate
EAA.TOT - monthly flows and loads	LoadUpdate
EAA.PRN - load summary	Terms
EAA.INV - sample inventory	Samples

The 'Terms' and 'Samples' pages provide supplementary information that is not used in compliance or load-reduction calculations. Only the first 9 of the 15 stations contained in the rainfall update file are used.

6. Click the "Reports" button to see results for any 12-month period, up to and including the most recent 12 months with complete data.
7. Click the "Graphs" button to view output graphs. Graph pages are located at the end of the workbook and are identified by page titles starting with 'C_' (e.g., 'C_Concs').

The above procedures can be followed to obtain routine updates. The basin files and workbook should be updated before updating farm-scale calculations.

If an error in the calculations is encountered during any of the macro steps, execution will stop and the Visual Basic code window will appear. The location of the error (breakpoint) will be highlighted in yellow. Note the error location. Reset the program by selecting 'Run Reset' from the Visual Basic menu. Return to Excel via the Windows 95 Task Bar (bottom of screen).

Basin Data Files

Data file structures are listed in Tables 2-4. The following constraints apply to data files used in phosphorus load calculations:

1. Flow, rainfall, and phosphorus data files must be sorted by date.
2. With the exception of the six supplementary stations contained in the rainfall file (EAA1-EAA5, PAIGE), the files should contain no missing values.

The above characteristics are automatically maintained by the updating procedure. The procedure checks for missing flow & rainfall data and does not permit the calculations to extend beyond the last date with complete rainfall & flow records. Dates are retrieved and stored in YYMMDD format. The software recognizes this format and will maintain correct sort order in data files extending beyond 1999. For example, April 20, 2000 will be stored as 000420 and will be recognized as a date occurring after December 22, 1998 (981222). Within the batch update procedure (GO.BAT, Table 6), the following steps are taken to update flow, rainfall, and phosphorus data files:

Function	Input File(s)	Program	Output File(s)
Archive Current Data	*.FIX	COPY	/ARCHIVE/*.FIX
Reformat Downloaded File	*.SPL	COPYFX	*.SPC
Create Update Table	*.SPC *.DAT	HYDTAB or RDTP	*.UPD
Create Backup Table	*.FIX	COPY	*.BAK
Append Update Table to Existing Table	*.BAK *.UPD	UPDATE	*.FIX
Calculate Monthly Total Rainfall	EAARAIN.FIX	MTOTAL	EAARAINM.FIX
Summarize Current Data	*.FIX	SCAN	*.SCN

where * = EAARAIN, EAAFLOW, or EAATP. In creating the new data base (*.FIX), all records in the backup table (*.BAK) on and after the first date in the update table (*.UPD) are replaced by records in the update table.

For the flow data set (EAAFLOW.FIX), the update table contains only records with complete data for all stations. The update period stops when the first missing flow value is encountered. In this way, missing values should never occur in the daily flow table. The EAATPLD program assumes that the flow data file contains no missing values.

A monthly rainfall table (EAARAINM.FIX) is created from the daily rainfall table (EAARAIN.FIX). Monthly values are assigned a missing value code if one or more daily rainfall value is missing. EAABASIN.XLS loads the monthly table, checks for missing values, and terminates the calculation interval at the end of the last month with complete rainfall data for all nine stations used in computing the basin-average rainfall. Data from six supplementary stations (EAA1-5,PAIGE) are contained in the EAARAIN.FIX file, but are not loaded into the EAABASIN.XLS workbook or otherwise used in the calculations.

Adding New Stations to Basin Calculations

The Rule requires adjustment of the calculations to reflect new inflows or outflows from the EAA. When this is necessary, the following measures should be taken:

1. Identify the appropriate DBKEY for flow data.
2. Edit EAAFLOW.COM to include the new DBKEY.

3. Add a line at the end of EAAFLOW.DAT to reflect the new DBKEY and a new flow station label. The flow station label is for descriptive purposes only.
4. Using a text editor, modify the backup daily flow file (EAAFLOW.BAK) to contain an additional column (on the right) with a width of 10 characters. Fill in all historical values (10/1/78--end of file) with 0's. Add a station label for this column in line 4; this should equal the label assigned in Step 3. Increase the column counter in Row 2 (currently, 13) by 1.
5. Edit the FLOWREAD subroutine in EAATPLD.FOR to handle the additional flow station. Follow the coding pattern established for other stations. Add a new flow station code at the end of the DATA statement in the FLOWREAD subroutine. These codes are referenced in the control file (EAA.JOB). Recompile the program.
6. Identify appropriate station and project codes for water quality data.
7. Edit EAATP.COM to include the new station and project codes.
8. Add a line to EAA.JOB to reflect the new station. Set the flow sign ("qsign") to 1 if positive flows stored in the DBKEY are to be used or to -1 if negative flows are to be used. Set the term sign ("tsign") to 1 for an outflow term or to -1 for an inflow/thruflow term. Set the composite sample flag ("compos") to 1 if composite samples are collected at the station or to 0, otherwise. The flow station code should be referenced to the code assigned in the DATA statement of the FLOWREAD subroutine in EAATPLD.FOR. The water quality station code should equal that referenced in EAATP.COM.

Once these steps are completed, follow the normal updating procedures describe above.

Freezing Basin Results

Most of the Rule compliance calculations are performed on the 'Monthly' page of the EAABASIN.XLS workbook. There is one row below the heading for each month after September 1978. Columns B-X contain input values for the month identified in Column A; these are retrieved from other pages of the workbook. Columns Y-BK contain results for the 12-month period ending in the current month. Columns BL-BU contain additional calculated fields used

in graphing results. Column BV indicates whether the corresponding row is frozen (1) or thawed (0). When the workbook is updated, new rows are appended to the monthly table using formulas stored in Row 120 (hidden from view).

When results for a recent water year (through April) have been certified, it is necessary to “freeze” the results. This operation ensures that previously-certified results do not change with future file updates. Small variations in historical load estimates might otherwise occur at stations relying on grab samples. Such variations reflect the following characteristics of the load-calculation algorithm specified in the Rule:

1. interpolation based upon date to estimate grab-sample concentrations between sampling dates; and
2. adjustment of grab-sample loads based upon the ratio of average grab-sample load to the average composite-sample load calculated from all data collected after September 1991.

Freezing is accomplished by converting formula cells in appropriate rows on the ‘Monthly’ page to fixed values.

The procedure of freezing results is located on the ‘Freeze’ page (Table 7). The user enters a year in the indicated cell; all results up to and including April of the specified year will be frozen. Clicking on the “Freeze Results” button completes the operation by converting all of the corresponding rows on the ‘Monthly’ page to fixed values. Formulas are retained in rows after April of the specified year.

In the event that results are frozen by mistake, results can be “thawed” by specifying an earlier year in the indicated cell. All results after April of the specified year will be thawed. This converts fixed values back to formulas, so that results will change with current and future file updates.

Freeze operations should be conducted by SFWMD staff on an annual basis after certification of results for a given water year. It will not be necessary to include the required macros in versions of the workbook distributed to the public. Once results have been certified and frozen, the ‘Freeze’ page can be deleted (optionally) from copies of the workbook distributed to the public containing certified results through the current year.

Farm-Scale Calculations

Overview

Table 8 lists and describes data files and programs involved in farm-scale calculations. Primary steps include:

1. Basin Calculations. Rainfall statistics needed for farm-scale calculations are extracted from the EAABASIN.XLS workbook. Basin calculations must be updated through the period used for summarizing farm results. This is accomplished using the procedures described above.
2. Farm Data Update. Files containing daily farm monitoring data (EAAWQDWN.OUT or EAAWQDWN.DAT) and pump calibrations (PUMPCAL.DAT) are updated by SFWMD staff. The farm data file can have either of two formats: (1) Original format (indicated by the extension .OUT); or (2) Revised (compressed) format (.DAT). A separate utility (RCONV.EXE) has been supplied to convert file formats (see below). Both the farm data file and pump-calibration file must be sorted by Structure & Date. Partial listings of these input files are given in Table 9.
3. Structure Data Reduction. A Fortran program (EAAFARM.FOR) calculates total flows and phosphorus loads by structure for a user-specified time interval (typically corresponding to one May-April Water Year).
4. Farm Data Reduction. Workbooks (EAAF####.XLS, ####= Year) calculate total loads by farm, perform rainfall adjustments, and test for compliance. Workbook contents are outlined in Table 10. Separate versions of the workbook are created and maintained for each Water Year. A separate Excel 97 workbook (FARMCODE.XLS) contains supporting macros (Visual Basic code), notes on installing and updating farm workbooks, a page index which describes the contents of each yearly farm workbook (Table 10), and documentation of any changes made in future software updates.

Once the update files (EAAWQDWN & PUMPCAL) have been acquired, all calculations are controlled from within the yearly farm workbook. To install the software on a PC, copy all files to single disk directory.

Installing Farm Software

The following procedures should be followed in the specified order to install the farm software and data files:

- 1) Create a new disk directory for farm files and copy all files to that directory. The software and data files require approximately ? megabytes of free disk space.
- 2) Install the basin software and update basin calculations, as described above.
- 3) Install the GIS data files (optional).
- 4) Run Excel & load the FARMCODE.XLS workbook.
- 5) On the 'Setup' page of FARMCODE.XLS, edit the disk directory names for farm files, GIS output files, and basin files. These values must be edited any time the file locations are changed.
- 6) Save FARMCODE.XLS (but do not close file).
- 7) Load a farm yearly workbook (e.g., EAAF1994.XLS).
- 8) If an explorer window appears looking for EAABASIN.XLS, navigate to basin directory & select EAABASIN.XLS.
- 9) The Farm workbook is linked to the Basin workbook through in formulas located on the 'Basin' page. Permanently update links from the Farm workbook to the Basin workbook using following Excel commands:
 - a) Select 'Edit Links' on the Farm workbook
 - b) Select the link to the EAABASIN workbook
 - c) Click 'Change Source..'
 - d) Navigate to the directory containing the EAABASIN workbook
 - e) Select the EAABASIN Workbook
 - f) Click 'OK'
 - g) Click 'OK'
- 10) Go to the Farm workbook 'Menu' page.
- 11) Save the farm workbook (EAAF1994.XLS).

Installation instructions are repeated on the 'Notes' page of the FARMCODE.XLS workbook.

Supporting macros are stored as Visual Basic Code attached to the FARMCODE.XLS workbook. These are transparent to the user. To view the code, select "Tools Macros VisualBasicEditor". Then select 'Modules/Module1' under VBA Project FARMCODE.XLS from the Project window in the upper left corner of the screen.

Additional supporting documentation is provided in the form of comments attached to individual cells in the farm workbook. Cells with comments are indicated by red triangles in the upper right hand corner. Move the cursor over the cell (without clicking the mouse) to view a comment.

Updating Farm Calculations

Periodic updates of the calculations will normally involve the following procedures in the specified order:

1. Load and update the EAABASIN.XLS workbook using procedures described above. Save and close the workbook.
2. SFWMD staff maintains a data base containing daily monitoring data submitted by permittees. Acquire the most recent farm data file (EAAWQDWN.OUT or EAAWQDWN.DAT) and copy it to the disk directory containing farm software. The program reads with either file format (.OUT or .DAT).
3. SFWMD staff maintains a data base of pump calibrations and operating date ranges for each structure. Acquire the most recent output file (PUMPCAL.DAT) and copy it to the disk directory containing the farm software.
4. Load the farm workbook produced for the previous water year. For example, if you are updating the calculations for water year 1996, load the EAAF1995.XLS workbook.
5. Edit the "Farm Data File" field on the "Constants" page of the farm workbook to reflect the name of the farm data file retrieved in Step 2 (EAAWQDWN.DAT or EAAWQDWN.OUT).

6. Click the 'Update Farm Baselines' button on the 'Menu' page. Respond "Yes" to the prompt. This procedure copies the updated farm baseline data in columns W..AA of the 'Results' page to columns C..G of the same page as fixed values.
7. Revise the 'Farms' page to reflect any new structures, farms, or calculation methods for the current water year (see Maintaining Farm Table, below).
8. Edit the "Ending Year", "Ending Month", "Case Title", and "Input File Name" fields on the 'Menu' page to reflect the new water year. For example, if the new water year is 1996, "Ending Year" = 1996, "Ending Month" = 4, "Case Title" = Water Year 1996, and "Input File Name =" EAAF1996.PRN.
9. Save the farm workbook with a new name reflecting the new water year (e.g., "EAAF1996.XLS") using the Excel "File Save_As" command. Once the new farm workbook has been created, steps 4-8 do not have to be repeated when updating calculations for a given water year.
10. Click the "Update Data Files" button on the 'Menu' page. This creates an input control file for structure calculations (AUTO.DAT) and executes a DOS batch file (AUTO.BAT). The EAAFARM.EXE program is executed to summarize results by structure for the specified period. Three output files are generated:

EAAF####.PRN - Results, one row per structure
 REC####.PRN - Daily values used in structure calculation
 CHK####.PRN - Error Messages, Flagged Records

where #### = Water Year. The REC and CHK files are for documentation purposes only; they are not referenced in subsequent calculations. The REC file is accessed by the PLOT utility described below. The CHK file should be viewed to identify potential errors in the EAAWQDN.OUT (or .DAT) file. Close the DOS window by clicking on the X in the upper right hand corner.

11. Click the "Update Workbook" button to update all tables in the workbook. This loads the structure file (EAAF####.PRN) created in the previous step, retrieves basin results, calculates farm totals, screens data for completeness, adjusts loads for variations in rainfall, and tests farm compliance. The algorithm is illustrated in Table 13

and Figure ?. The progress of the calculations is shown by the status indicator in the lower left hand corner of the screen. A pop-up window appears when the calculations are complete. Close the window to proceed with the next step.

12. Click the "Output Summary" button on the 'Menu' page or the 'Outputs' tab to view a summary of results. An example is given in Table 12.
13. Click the "Create GIS Files" button on the 'Menu' page to create GIS output files for display using ArcView Version 3.0 (ESRI). An ArcView Project file (EAA.APR) is provided for this purpose (see GIS Output). This step is optional if GIS output is not desired.
14. Click the "Results for One Farm" button on the 'Menu' page to view a summary of results for a particular farm (UAID). This procedure switches to the 'One Farm' page. The requested UAID can be entered in Cell C21. Clicking the "Results" button updates the tables on this page. Clicking the "Next" or "Last" button increases or decreases the UAID number and updates the tables. Clicking the "Menu" button returns to the 'Menu' page.
15. Navigate to the 'Results' page to view a summary of results for all UAID's (one line per farm). The 'Results_C' page contains data in a similar format but excludes farms with rejected data for the current water year.
16. Click the "View Graphs" button to view output graphs summarizing farm results by EAA sub-basin and comparing farm results with basin results.
17. Save the workbook labeled with the current water year (e.g., EAAFARM96.XLS).

Table 13 summarizes the algorithms used for calculating structure and farm loads.

If an error in the calculations is encountered during any of the macro steps, execution will stop and the Visual Basic code window will appear. The location of the error (breakpoint) will be highlighted in yellow. Note the error location. Rset the program by selecting 'Run Reset' from the Visual Basic menu. Return to Excel via the Windows 95 Task Bar (bottom of screen).

Maintaining the Farm Pump Calibration File

The pump calibration file (PUMPCAL.DAT) contains pump calibration values for specified structures and time periods. The format of the file is shown in Table 9. Each structure must be registered in this file before it can be used in calculating structure and farm loads. File contents include structure code, calibrated flow, first date, and last date. The specified date ranges are inclusive. The file must be sorted by structure code and first date. If the first date on each line should contain a valid date in YYYYMMDD format. If the last date is blank, the corresponding calibrated flow applies to all dates after and including the first date. A flow value of -999 is used to indicate a period when the structure was not in operation. Any records encountered during such a period will be ignored. Farms will not be penalized for missing data during a period when the structure is not operational. Each structure is assumed to be non-existent (-999 implied) for all dates prior to the first entry in the pump calibration file. According to the data-reduction algorithm shown in Table 13, calibrated flow is used to estimate flows on missing dates only if the zero flow was reported on all other dates in the calculation interval.

Maintaining the Farm Table

Farm totals are calculated on the 'Farms' page of EAAF####.XLS. Rows are grouped and sorted by Farm or Unit Area Id (UAID). New structures can be added (or removed) by inserting (or deleting) rows in the table at locations adjacent to other structures referenced to the same UAID. The following general rules apply to maintenance of the farm table:

1. The table is sorted by UAID. The first record for each UAID should contain the total results for that UAID.
2. Values in Columns A-K are input cells that must be directly entered, as appropriate.
3. Column E should contain a drainage area value for each line with a GIS-ID code. In addition, in the first line for each UAID, Column E should contain the total area for that UAID. This value may be entered directly (if there is only one GIS-ID for the UAID). Otherwise, the total area should be computed as the sum of the areas for all GIS-ID's in the UAID.
4. Entries in Columns H-K (Early Baseline, Date Ranges, Comments) are for reference purposes only and are not used in the calculations. Data ranges used in the calculations are contained in the Pump Calibration file.

5. Columns L-AC are formula cells. These can be copied from Range L8..AC8 to any new rows inserted into the table. Subsequent editing of these formulas may be required, depending on calculation method, as described below.
6. Columns L-Q retrieve structure results from other portions of the workbook.
7. Columns R-W calculate farm totals (area, flow, load, adjusted load) based upon structure results stored in Columns L-O.
8. Columns R-Y should contain entries only in the first row for each UAID.
9. Column R (Total Farm Area) should always be set equal to Column E.
10. Columns S-W may be edited to reflect any special rules for combining structure results (adding or subtracting results from more than one structure). In some cases (depending upon calculation method), calculating farm totals may involve subtracting results for one group of structures from results for another group of structures. Examples are given in formulas for UAID's 4, 68, 102, & 113.
11. Columns V & W calculate the sums of total load and sampled load for all structures used for the current UAID (regardless of whether a subtraction occurs). These columns are used to calculate the percent of the total load that is sampled for each UAID.
12. If any structures present in previous years are eliminated, the corresponding summation formulas in Columns S-W must be adjusted accordingly. Columns R-Y should contain only one row for each UAID
13. Columns Z-AC contain record selection criteria and scratch variables. These columns are automatically updated when the 'Update Workbook' button is pressed; therefore, these columns can be ignored when adding or deleting records from this table.
14. A "1" can be entered in Column Y to force acceptance of data from a particular UAID (i.e., override data rejection criteria specified on the 'Constants' page). This column is normally left blank. This is provided to accommodate special situations. Entries in Column Y reflecting prior year's calculations should be cleared before starting calculations for a new year.

Document any changes in calculation methods on the 'Methods' page of the farm workbook. The revision log begins in Row 21 of the 'Methods' page. Changes are identified by Water Year.

If new structures or UAID's are added to the Farm table, or if the structure assignments to UAID's are changed, the structure index file used by the Plot Utility (STRUCS.DAT) must be edited to reflect these changes (see Plot Utility).

File Conversion Utility

The utility 'RCONV.EXE' translates farm daily data files in the original format (EAAWQDWN.OUT) to the revised format (EAAWQDWN.DAT). It is executed with the following command line:

```
>RCONV Infile Outfile
```

where,

Infile = Input File Name, typically = EAAWQDWN.OUT
 Outfile = Output File Name, typically = EAAWQDWN.DAT

Record Counting Utility

The utility 'RCOUNT.EXE' reads the farm daily data file (.OUT or .DAT format) and produces an output table indicating the number of records and date range for each structure. It is executed with the following command line:

```
>RCOUNT Infile Outfile
```

where,

Infile = Input File Name, typically = EAAWQDWN.OUT or .DAT
 Outfile = Output File, typically 'RCOUNT.PRN'

Plot Utility

A separate utility has been provided for plotting farm daily rainfall, flow, concentration, and/or load data. Missing and estimated values are indicated. Plots can be displayed on the screen or printed using any laser-jet compatible printer directly connected to the PC (probably won't work through network). Plot data are taken from the REC####.PRN files created by EAAFARM.EXE.

To execute the utility, enter the following command from the DOS prompt:

```
>PLOT YEAR UAID
```

where,

YEAR = year (1994, 1995, ,1996, etc) (required)

UAID = Unit Area ID Number (optional)

If UAID is 0 or blank, data from all structures will be plotted. If UAID is specified, the utility reads a separate index file (STRUCS.DAT) to find structure codes associated with the specified UAID. This index file must be updated manually if new structures or UAID's are created. Plot instructions are contained in the ASCII file 'PLOT.DAT'. By editing this file, the user can:

- Direct output to screen or printer
- Select early baseline farms, non-early baseline farms, or both
- Select date range within the specified year
- Select plot variables (rainfall, flow, conc., and/or load)
- Change plot size, colors, etc

The last line of the PLOT.BAT file should be edited to reflect the disk directory containing farm data files. A README file provides further documentation.

Outlier Utility

A utility for identifying possible outliers in the farm data set is also provided. The program reads data directly from the EAAWQDWN.OUT file. The ASCII input file 'OUTLIERS.DAT' can be edited to specify the following:

- input file name & directory
- date range
- output file names
- minimum concentration for outlier screening = C_{\min}
- significance level for outlier detection

The utility can be executed by entering the following command from the DOS prompt:

```
>OUTLIERS
```

The program loads and tests data from each structure. Three output files are created:

DAILY.PRN	listing of data from all days with positive flow
EVENTS.PRN	listing of event-mean concentrations & flows
OUTLIERS.PRN	listing of outliers & significance levels

Outliers are detected based upon deviation from a log-scale regression relating event-mean concentration to event-mean flow for each structure. Events are terminated when the reported daily concentration changes. The algorithm is similar to that used for detecting outliers in basin load calculations. The regression model is of the following form:

$$\text{LOG}(C^*) = a + b \text{LOG}(Q)$$

C^*	= Maximum (C , C_{\min})
Q	= Event-Mean Flow (cfs)
C	= Reported Concentration (ppm)
C_{\min}	= Minimum Concentration (ppb)

C_{\min} is specified in the input file (OUTLIERS.DAT). This term is included to reduce negative skewness which occurs in the log-scale concentration distribution when very low concentrations are reported. A C_{\min} value of 0.02 ppm is suggested.

The utility is provided to assist in checking the farm data and correcting typographic errors. Flagged values are not necessarily unrepresentative. They should be checked to ensure that unusually low or high values do not reflect typographic errors in the source data set. The PLOT utility can provide additional perspectives on flagged values. There is no provision in the existing methodology to delete values solely based upon outlier detection. A README file provides further documentation.

ArcView Project for Displaying Farm Results

An ArcView 3.0 project file named 'EAA.APR' is distributed with the farm software. It is beyond the scope of this report to provide instructions for using ArcView. The project contains two views (Farms & Structures).

The 'Farms' view shows results in the form of polygons representing UAID's. The GIS attribute table representing the farm boundaries is joined to the farm output file for each year (e.g., FARM94.DBF). The Farm view contains themes

for displaying unit runoff, concentrations, and unit area loads in each year.

The 'Structures' view shows results in the form of points representing structure locations. The GIS attribute table representing structure locations is joined to the structure output file for each year (e.g., STRUC94.DBF). The structure view contains themes for displaying structure concentrations in each year.

The following procedures should be followed for updating the ArcView project when output files for a new water year are available (e.g. 1998).

- 1) Add new data tables.
 - a) From main project menu, select 'Tables', then 'Add'.
 - b) Navigate to data base file for next year (FARM98.DBF) & select file.
 - c) Select 'Add' again.
 - d) Navigate to structure data base file for next year (STRUC98.DBF) & select file.

- 2) Update 'Farms' View.
 - a) Select 'Views' Window (top of left panel) Update Farms View.
 - b) Select 'Farms' View
 - c) Select Theme labeled 'Concs 1997' from left panel.
 - d) Select 'Edit CopyThemes'
 - e) Select 'Paste'
 - f) Select new theme at top of window (still labeled 'Concs 1997')
 - g) Select 'Themes Properties', change Theme Name to "Concs 1998", & click 'OK' to close themes window.
 - h) Select 'Themes Table'. A table called 'Attributes of ...' will appear.
 - i) Link the Attributes table to the new data file:
 - i) Select 'Table Remove All Joins'.
 - ii) Move cursor to top of column labeled 'GIS_ID'. Click on label. It should turn dark grey. (It may already have been selected.)
 - iii) Minimize window clicking on the '-' in the upper right hand corner.
 - iv) From the Table window, select the new data base file (FARM98.DBF).
 - v) Move cursor to top of column labeled 'GIS_ID'. Click on label. It should turn dark grey.
 - vi) Maximize the previous table window (Attributes of ...).
 - vii) Select 'Table Join'. Check to make sure that the 1997 results have been added to the right hand side of the attribute table.
 - viii) Close Table window.
 - j) Select 'Views' Window
 - k) Select 'Farms' View
 - l) Double click on the theme labeled 'Concs 1998'.

- m) Under 'Legend Type' select 'Graduated Color'
 - n) Under 'Classification Field' select 'Conc'
 - o) Click on the 'Apply' box, then close window.
 - p) The view should now contain concentration values for 1998.
- 3) To create a view for 1998 runoff:
- a) Select the 'Concs 1998' theme.
 - b) Select 'Edit Copy Themes'.
 - c) Select 'Edit Paste'
 - d) Select the copied theme at the top of the menu.
 - e) Select 'Themes Properties', change Theme Name to "Runoff 1998", & click 'OK' to close themes window.
 - f) Double click on the theme labeled 'Runoff 1998'.
 - g) Under 'Classification Field' select 'Runoff'
 - h) Under 'Color Ramps' select a color scheme.
 - i) Click on the 'Apply' box, then close window.
 - j) The view should now contain runoff values for 1998.
- 4) Repeat the previous procedure to establish a view for Unit Area Load or other variable in the output data file.

Procedures for updating the 'Structures' view are analogous to those described above for the 'Farms' view. In the Table Join step, select the 'Struc_id' field from the Attributes Table and the 'Structures' field from the data (STRUC98.DBF) table.

Summary of Farm & Basin Results

The Excel workbook 'FARMSUM.XLS' provides summaries of farm and basin results for each year. This file is copies results from each yearly farm workbook. Three data views are provided:

1. Cross-tabulation of farm results by UAID and year for several variables extracted from the 'Results' page of the yearly farm workbooks (e.g., Table 14)
2. Summary of all results for each year and a single UAID (e.g., Table 15)
3. Summary of farm & basin results for each year (e.g., Table 16)

Instructions for installing and updating the file are contained on the first page of the workbook. The workbook is updated by clicking on the 'Update

Workbook' button located on the 'Notes' page. This executes a macro (stored in FARMCODE.XLS) which copies the 'Outputs' and 'Results' pages of each yearly farm workbook to pages of FARMSUM.XLS named SUM#### and EAAF####, respectively. All water years with valid workbooks (starting with 1994) are copied. Formulas are converted to constants, so that FARMSUM.XLS is transportable and contains no 'live' linkages to the yearly farm workbooks. The copied pages are stored before the 'Notes' page. Summary tables are located after the 'Notes' page. Summary tables must be edited when a new water year is added, following the instructions contained on the 'Notes' page.

List of Figures

Table 7 Freeze Procedure

Location: 'Freeze' Page

Freeze Results

FREEZING converts
Normally, this would

and monthly values to constants, so that they won't change with future file updates
once results for current water year have been certified.

Enter Water Year (YYYY)----->

1996

results will be frozen through April of this year
& thawed after April of this year
Value must be between 1993 & last water year
with complete data = 1997

Freeze Results

[<-- Press Here to Freeze Results](#)

Modifies rows in Monthly Worksheet. Frozen Rows have black text. Thawed Rows have red text.

Workbook Updated Thru	199709
Results Currently Frozen Thru	199604
Number of Frozen Rows	211
Number of Active Rows	17
Total Number of Valid Rows	228

Adjusted Load	mtons	204.5	77.7	75.4	28.4	22.9
Flow-Wtd-Mean Conc	ppb	176	233	171	134	143
Runoff	inches	37.7	42.7	36.3	49.7	23.9
Unit Area Load	lbs/acre	1.51	2.25	1.40	1.51	0.78
Adjusted Unit Area Load	lbs/acre	2.12	3.03	2.42	1.57	1.07

Note: results by sub-basin generated from structure data

Table 13
Algorithm for Calculating Structure & Farm Loads

Definitions:

Structure Effective Date = First Date in Pump Calibration File Within Current Year
Mean Positive Flow = Average Reported Flow on Days when Flow > 0

For Each Day of Year and Structure:

```
If (Calibrated Flow = -999) then
    Assume Structure Did Not Exist
    Flow = 0.

Elseif (Flow Reported) then
    Flow = Flow Reported

If (Date >= Effective Date & Conc Reported) then
    Flow Sampled = Flow Reported
    Load Sampled = Flow Reported x Conc Reported
else
    Flow Sampled = 0
endif

Elseif (Mean Positive Flow Defined) then
    Flow = Mean Positive Flow

Else
    Flow = Calibrated Flow
    [ This will only happen if reported flows all = 0 or missing ]

Endif
```

Totals for Year and Structure:

Flow-Weighted-Mean Conc = Total Load Sampled / Total Flow Sampled
Total Load = Flow-Weighted-Mean Conc x Total Flow

Totals for Year and Farm:

Total Farm Load = Sum of Structure Total Loads
Total Farm Flow = Sum of Structure Total Flows
Sampled Total Flow = Sum of Structure Total Sampled Flows
% of Flow Sampled = Total Sampled Flow / Total Flow

Reject Farm Data if Percent of Flow Sampled < 75%

For Farms with Loads Calculated by Difference (UAID's 3, 5, 6, & 11):

Total Farm Load = Downstream Farm Load - Upstream Farm Load
Total Farm Flow = Downstream Farm Flow - Upstream Farm Flow
% of Flow Sampled = Downstr. Farm Sampled Flow / Downstream Farm Total Flow

Table 14
